

ABSTRACT

A medical data warning notifying system and method for notifying a hospital only when there is abnormal data in medical data entered by a patient on peritoneal dialysis at home. In the medical data warning notifying system, a patient terminal used by a patient, a server for controlling data exchanged between the patient and a hospital, and a hospital terminal used by a doctor are interconnected over a network. The server receives medical data entered through the patient terminal, stores the received medical data, and judges from the received medical data whether or not there is any abnormal data. If it is judged that abnormal data is included, a warning signal is sent to the hospital terminal. A message created on the hospital terminal is relayed and sent to the patient terminal.
